(46-50) Read the given passage carefully

For environmentalists who worry already how often they fly, how much rubbish they throw out and what sort of groceries they buy, here is something else to fret about: how much power that computer over there is using, even as it browses the Greenpeace website. Relax: the main problem is not the computer you keep at home. Most of those are fairly frugal. A typical desktop and monitor together use perhaps 150 watts, and in "sleep" mode the consumption could be as little as 20 watts. An electric oven uses several thousand. If you want to cut power consumption (whether to save the planet or to save money), look first to air-conditioning, heating and hot water, and then to the efficiency of appliances.

All that said, turning a computer off at night would certainly do no harm (though it might not be best for the computer).

The gas-guzzlers of the computer world are the big servers that big firms use to store big data. They gobble up 4% of all electricity consumed in America according to Logicalis, an IT consultancy. And their ranks are swelling fast. The number of servers in the world has doubled since 2000. Each new generation of servers is bigger and more power-hungry than the last. They consume more power, they generate more heat, they demand more air-conditioning that sucks up yet more juice. As much as 70% of the power used by a typical firm in a service industry is due to its servers, says Tom Kelly, the boss of Logicalis. The trend is not lost on the biggest names in the tech business. On January 27th, both Intel and IBM announced separately that they had found ways to make computer chips much more energy efficient. Google, Yahoo! and Microsoft are all building server farms near hydroelectric plants to ensure cheap, reliable power supplies. Chipmakers such as AMD and Intel have begun to tout not only the raw processing power of their wares, but also the processing power per watt.
